1 Problem 2 **COMPLETED**

Determine the first and second derivative with respect to x of: $f(x) = \frac{1}{1+e^{-x}}$

1.1 Solution to Problem 2

First Derivative:

$$f(x) = (1 + e^{-x})^{-1}$$

Using Chain Rule

$$f'(x) = -1(1 + e^{-x})^{-2} \times -1e^{-x}$$

$$f'(x) = \frac{e^{-x}}{(1 + e^{-x})^2}$$

Second Derivative:

$$f'(x) = \frac{e^{-x}}{(1 + e^{-x})^2}$$

Using Quotient Rule of Differentiation

$$g(x) = e^{-x} \quad h(x) = (1 + e^{-x})^2$$

$$g'(x) = -e^x \quad h'(x) = -2e^{-x}(1 + e^{-x})$$

$$f''(x) = \frac{h \times g' - g \times h'}{g^2}$$

$$f''(x) = \frac{-e^{-x} \times (1 + e^{-x})^2 + 2e^{-2x} \times (1 + e^{-x})}{e^{-2x}}$$

$$f''(x) = \frac{e^{-2x} - 1}{e^{-x}}$$

2 Problem 3 **COMPLETED**

If I break a stick of unit length into three random pieces, what is the expected length of the largest piece? (You may need to state the assumptions that you make.)

2.1 Solution to Problem 3

Let the stick be broken at two points X and Y .

Therefore, we have two independent random variables X, Y which are both uniform in $[0,1]$.

Let $A = \min(X, Y)$, $B = \max(X, Y)$ and $C = \max(A, 1 - B, B - A)$.

Let $f_C(a)$ be the probability density function (pdf) of C and $F_c(a)$ be the cumulative distribution function (cdf). Then:

$$F_c(a) = P(C \leq a) = P(A \leq a, 1 - B \leq a, B - A \leq a)$$

The cdf for the unit square is then equivalent to:

$$F_c(a) = \begin{cases} (3a - 1)^2 & : \frac{1}{3} \leq a \leq \frac{1}{2} \\ 1 - 3(1 - a)^2 & : \frac{1}{2} \leq a \leq 1 \end{cases}$$

Then the pdf is:

$$f_c(a) = \begin{cases} 6(3a - 1) & : \frac{1}{3} \leq a \leq \frac{1}{2} \\ 6(1 - a) & : \frac{1}{2} \leq a \leq 1 \end{cases}$$

Therefore, the expected length of the largest piece (C) is:

$$\int_{\frac{1}{2}}^{\frac{1}{3}} 6a(3a - 1)da + \int_1^{\frac{1}{2}} 6a(1 - a)da = \frac{11}{18}$$

3 Problem 8 **COMPLETED**

What are the values of the constants a , b and c if one writes the following expression in the form: $a(x - b)^2 + c$

$$3x^2 - 4x + 5 \quad (1)$$

3.1 Solution to Problem 8

$$3(x^2 - \frac{4}{3}x + \frac{5}{3})$$

$$3\left[(x - \frac{2}{3})^2 - \frac{4}{9} + \frac{5}{3}\right]$$

$$3\left[(x - \frac{2}{3})^2 + \frac{11}{9}\right]$$

$$3(x - \frac{2}{3})^2 + \frac{11}{3}$$

$$a = 3; \quad b = \frac{2}{3}; \quad c = \frac{11}{3}$$

4 Problem 6 **COMPLETED**

A factory that makes light bulbs contains three machines. The machines manufacture 20%, 30% and 50% of the total production. From their production, 5%, 4%, and 2% respectively are faulty. I choose a collection of light bulbs at random from the output.

4.1 Solution to Problem 6a

If the collection contains two faulty light bulbs, what is the probability that they come from the same machine?

Let $P_{M_{Af}}$ represent Probability of faulty bulbs produced from the first machine (A).

Similarly for second machine and third machine we have $P_{M_{Bf}}$ and $P_{M_{Cf}}$ respectively.

$$P_{M_{Af}} = \frac{5}{20}; \quad P_{M_{Bf}} = \frac{4}{30}; \quad P_{M_{Cf}} = \frac{2}{50}.$$

Let the probability that two faulty light bulbs from a collection come from the same machines be $P_{M_{2f}}$.

$$P_{M_{2f}} = \left(\frac{5}{20} \times \frac{5}{20}\right) + \left(\frac{4}{30} \times \frac{4}{30}\right) + \left(\frac{2}{50} \times \frac{2}{50}\right) = 0.00163$$

4.2 Solution to Problem 6b

Let the probability that the three faulty light bulbs from a collection come from the different machines be $P_{M_{3f}}$.

$$P_{M_{3f}} = \left(\frac{5}{20} \times \frac{4}{30} \times \frac{2}{50}\right) = \frac{1}{750}$$

5 Problem 4 ****COMPLETED****

The twenty-first century began on 1 January 2001 (a Monday) and will end on 31 December 2100 (a Friday). What percentage of twenty-first century Wednesdays fall on the last day of a month? (This question requires some coding.)

5.1 Solution to Problem 4

The Python code snippet is shown in Figure 1. Percentage of the 21st century Wednesdays that fall on the last day of the month:

$$\begin{aligned} &= \frac{172}{5242} \times 100\% \\ &3.3\%(1dp) \end{aligned}$$

The screenshot shows a Jupyter Notebook titled 'Untitled13' with a last checkpoint 8 minutes ago. The code in the cell is as follows:

```
In [54]: import calendar                                     #Python Calendar module
all_wednesdays = 0
last_wednesdays = 0
cal= calendar.Calendar()

for year in range(2001, 2101):                                #set range for the 21st century
    for month in range(1,13):
        last_day_month = calendar.monthrange(year,month)[1]    #get the Last day of each month per year

        if (calendar.weekday(year, month, last_day_month)) == 4: #check if the last day is a wednesday
            last_wednesdays = last_wednesdays + 1             # if the check above is true increment the counter

        for day in cal.itermonthdays(year,month):
            if day > 0:
                if (calendar.weekday(year, month, day)) == 4:   #check for wednesday per month per year
                    all_wednesdays = all_wednesdays + 1

        if calendar.isleap(year):                                #check for Leap year and add one more wednesday to it.
            all_wednesdays = all_wednesdays + 1

print(all_wednesdays,last_wednesdays)

5242 172
```

The output of the code is '5242 172'. The Jupyter interface includes a menu bar (File, Edit, View, Insert, Cell, Kernel, Widgets, Help) and a toolbar with various icons for file operations and code execution. The bottom of the image shows a Windows taskbar with the search bar and several application icons.

6 Problem 1

Each night, a princess is equally likely to sleep on anything from six to twelve mattresses. On half of the nights of the year, a pea is placed underneath the lowest mattress. She never falls asleep if a pea is placed underneath a pile of six mattresses. If the pea is placed underneath seven mattresses, she sleeps wonderfully one night out of ten; under eight mattresses, she sleeps well two out of ten nights; and so on, until if the pea is placed underneath the full twelve mattresses, she sleeps well six out of ten nights. One morning, when her good friend Bayes woke her up, she said that she had slept incredibly well that night! What is the expected number of mattresses upon which she slept?

6.1 Solution to Problem 1

The expected value (or mean) of X , where X is the expected number of mattresses is a discrete random variable. Let the expected value of X be written as $E(X)$.

Number of mattresses, S	6	7	8	9	10	11	12
isAsleep?	no	yes	yes	yes	yes	yes	yes
Probability of good sleep with pea, $P(X = x)$	0	$\frac{1}{10}$	$\frac{2}{10}$	$\frac{3}{10}$	$\frac{4}{10}$	$\frac{5}{10}$	$\frac{6}{10}$

$$E(X) = S \times P(X = x)$$

$$= 6 \times P(X = 6) + 7 \times P(X = 7) + 8 \times P(X = 8) + 9 \times P(X = 9) + 10 \times P(X = 10) + 11 \times P(X = 11) + 12 \times P(X = 12)$$

$$= 0 + \frac{7}{10} + \frac{16}{10} + \frac{36}{10} + \frac{40}{10} + \frac{55}{10} + \frac{72}{10}$$
